

Revealing satellites and streams in the Local Volume with LSST

Jeff Carlin

AURA/Vera C. Rubin Observatory

LSST

Legacy Survey of Space and Time

The Vera C. Rubin Observatory

The Vera C. Rubin Observatory is located on Cerro Pachón in Chile. The Simonyi Survey Telescope's primary mirror has a 6.7 meter *effective* diameter and its camera a 9.6 deg² field-of-view and six optical-NIR filters: *ugrizy*.

Once construction and commissioning are complete, Rubin Observatory will execute the 10-year Legacy Survey of Space and Time (LSST):

- single-image depths (point source; AB)
 - *ugrizy* = 23.9, 25.0, 24.7, 24.0, 23.3, 22.1 mag
- 10-year LSST depths (point source; AB)
 - *ugrizy* = 26.1, 27.4, 27.5, 26.8, 26.1, 24.9 mag

See Ivezić et al. (2019) for technical details about the design and the science goals.

Survey Strategy Basics

One of the most recent baseline survey simulations.

The **Baseline Survey Strategy** was designed to meet the basic requirements to achieve the core science goals of the **Legacy Survey of Space and Time** (LSST; requirements described in ls.st/srd).

Baseline design elements for the WFD area:

- should cover at least 18000 deg²
- average of 825 visits per field over 10 years
- same-night same-field re-visit “pairs”

Additional areas covered should include:

- at least 5 deep drilling fields
- the North Ecliptic Spur, the Galactic Plane, and the South Celestial Pole

How to optimize the LSST to maximize scientific return is an open question.

huge facility

large aperture, fast telescope

3.2 Gpixel camera with large field of view

Data and compute sizes:
 Final volume of raw image data = 60 PB
 Final catalog size (DR12) = 25 TB
 Peak compute power in Rubin Observatory data centers
 = about 2 PFCOPS

Network bandwidth:
 Summit (Core/Facility) - Base (La Serena) = 600 Gbps
 Base (La Serena) to Archive (SLAC) = 2 x 200 Gbps

Alert Production:
 Real-time alert latency = 60 seconds
 Estimated number of alerts per night = up to about 25 million

Data Releases:
 Number of Data Releases = 11
 Images collected = 3.3 million 3.2 Gpixel images

Estimated counts for DR1
 (produced from first 3 months of observing)
 Objects = 18 billion; Sources = 150 billion (single events); Forward Sources = 1.75 billion

Estimated counts for DR11
 Objects = 27 billion; Sources = 7 billion (single events); Forward Sources = 30 billion

LSST Data Products

Difference Image Analysis (DIA)

Alert Production. Raw images are processed, a template is subtracted, and difference-image sources are detected, associated, characterized, and...

...distributed as alerts to brokers, where they can be rapidly analyzed by users.

Prompt Products. Images and catalogs from DIA.

Data Release. Deeply coadded images & associated catalogs, plus DIA products.

The Prompt and Data Release data products will be available to users via the Rubin Science Platform.

Opportunities and challenges*

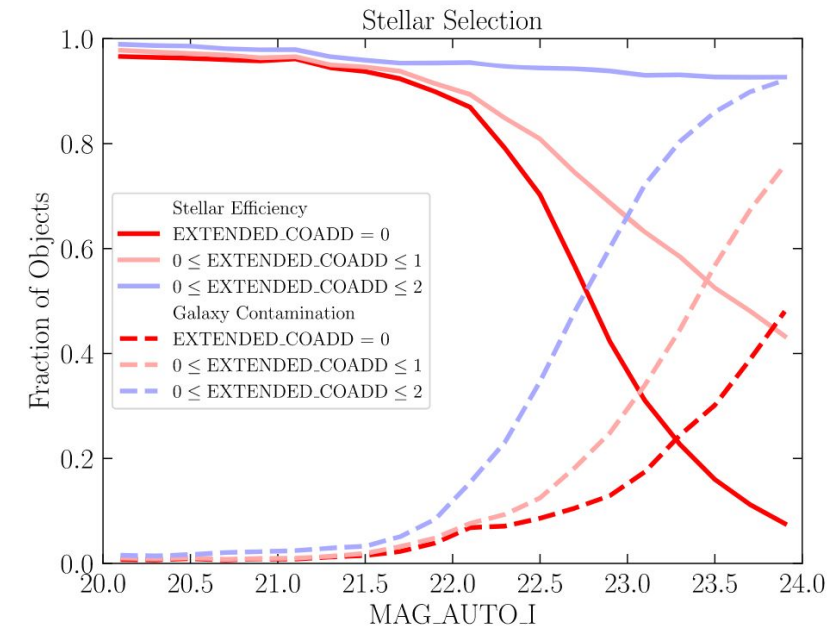

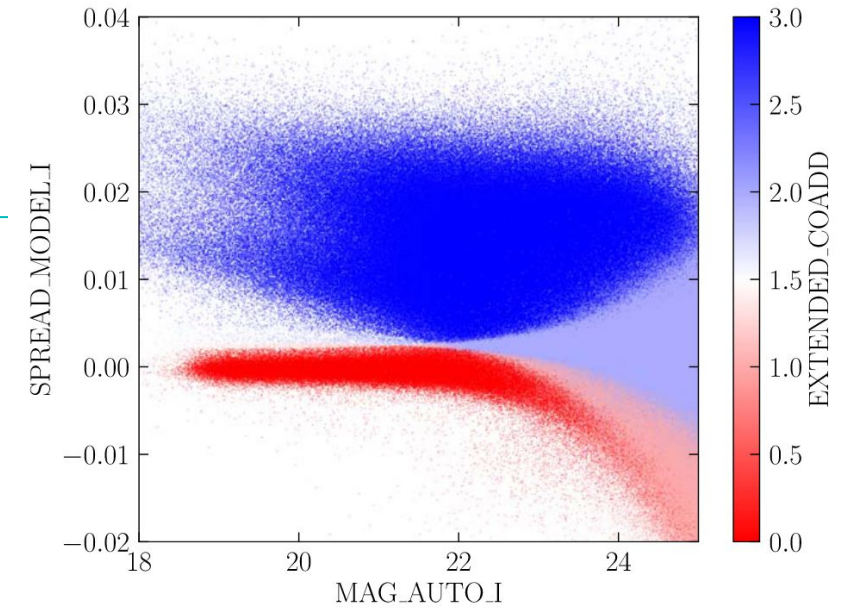

- Star/galaxy separation at the faint end
 - Detection of “partially resolved” systems (and “isolated” dwarfs)
 - Detection of fuzzy blobs
 - Finding blue, star-forming dwarfs
 - Prioritizing follow-up (we can’t follow up everything!)
 - Optimizing background subtraction for LSB science
 - Characterizing the survey data (e.g., how survey properties affect matched-filter maps – see Ferguson poster)
 - Synthetic Source Injection for characterization (and for precursor studies)
 - Photometry in crowded fields/regions
 - Proper motions
- ...and doing all of this over $\sim 18000 \text{ deg}^2$ of sky
- Are models/simulations detailed/sophisticated enough to enable interpretation of LSST results?

Star/galaxy separation

Current LSST pipelines use PSF/cmodel flux ratio to determine “extendedness”

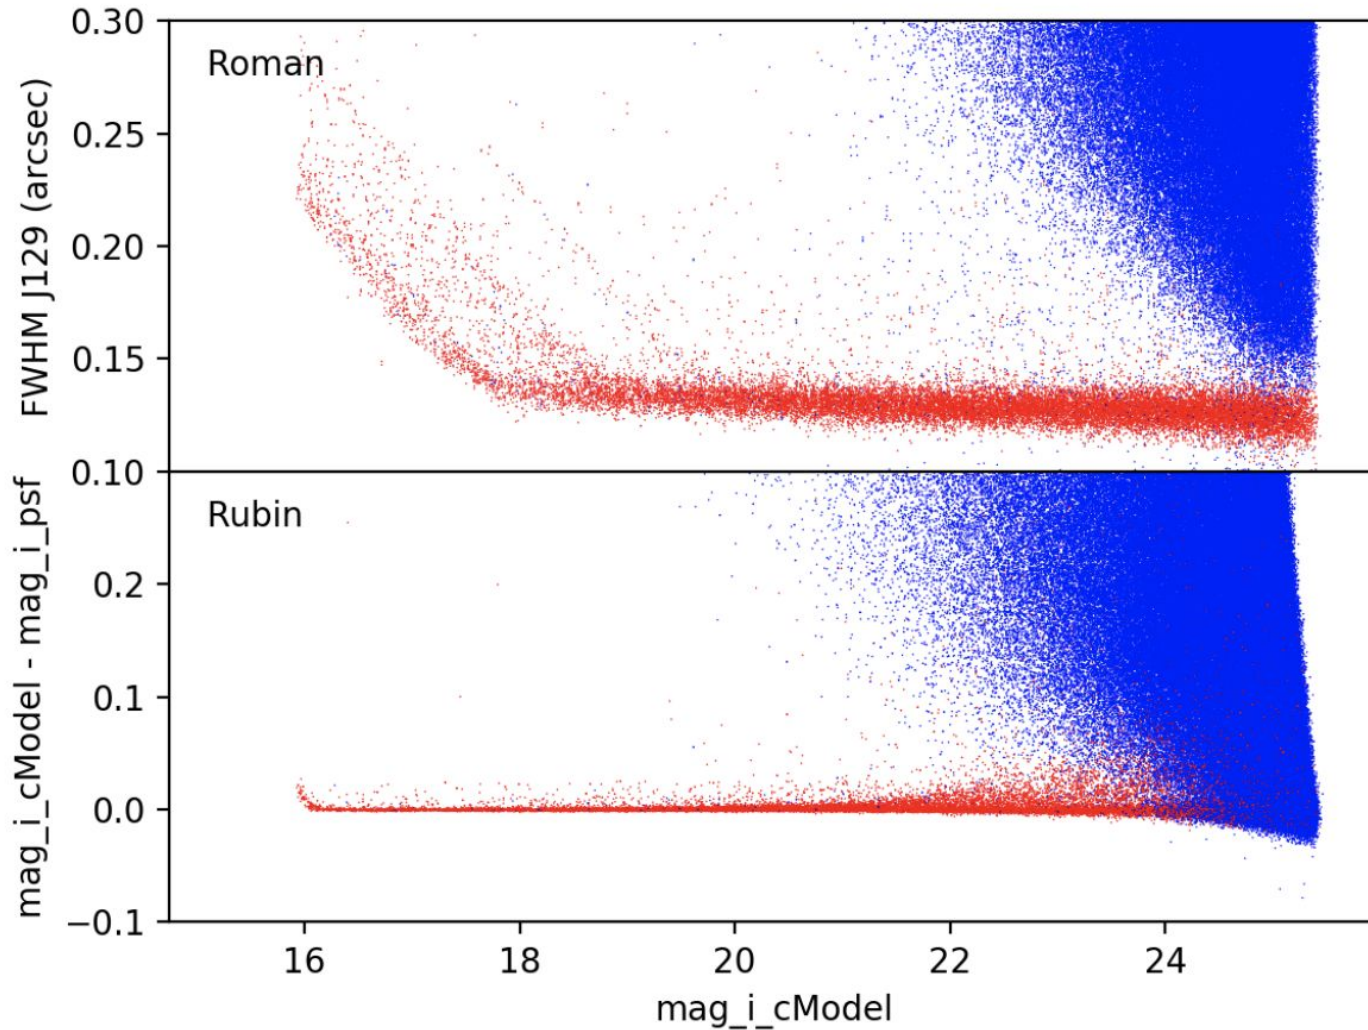

Carlin+, in prep

Abbott+2021 (ApJS, 255, 20; DES DR2)

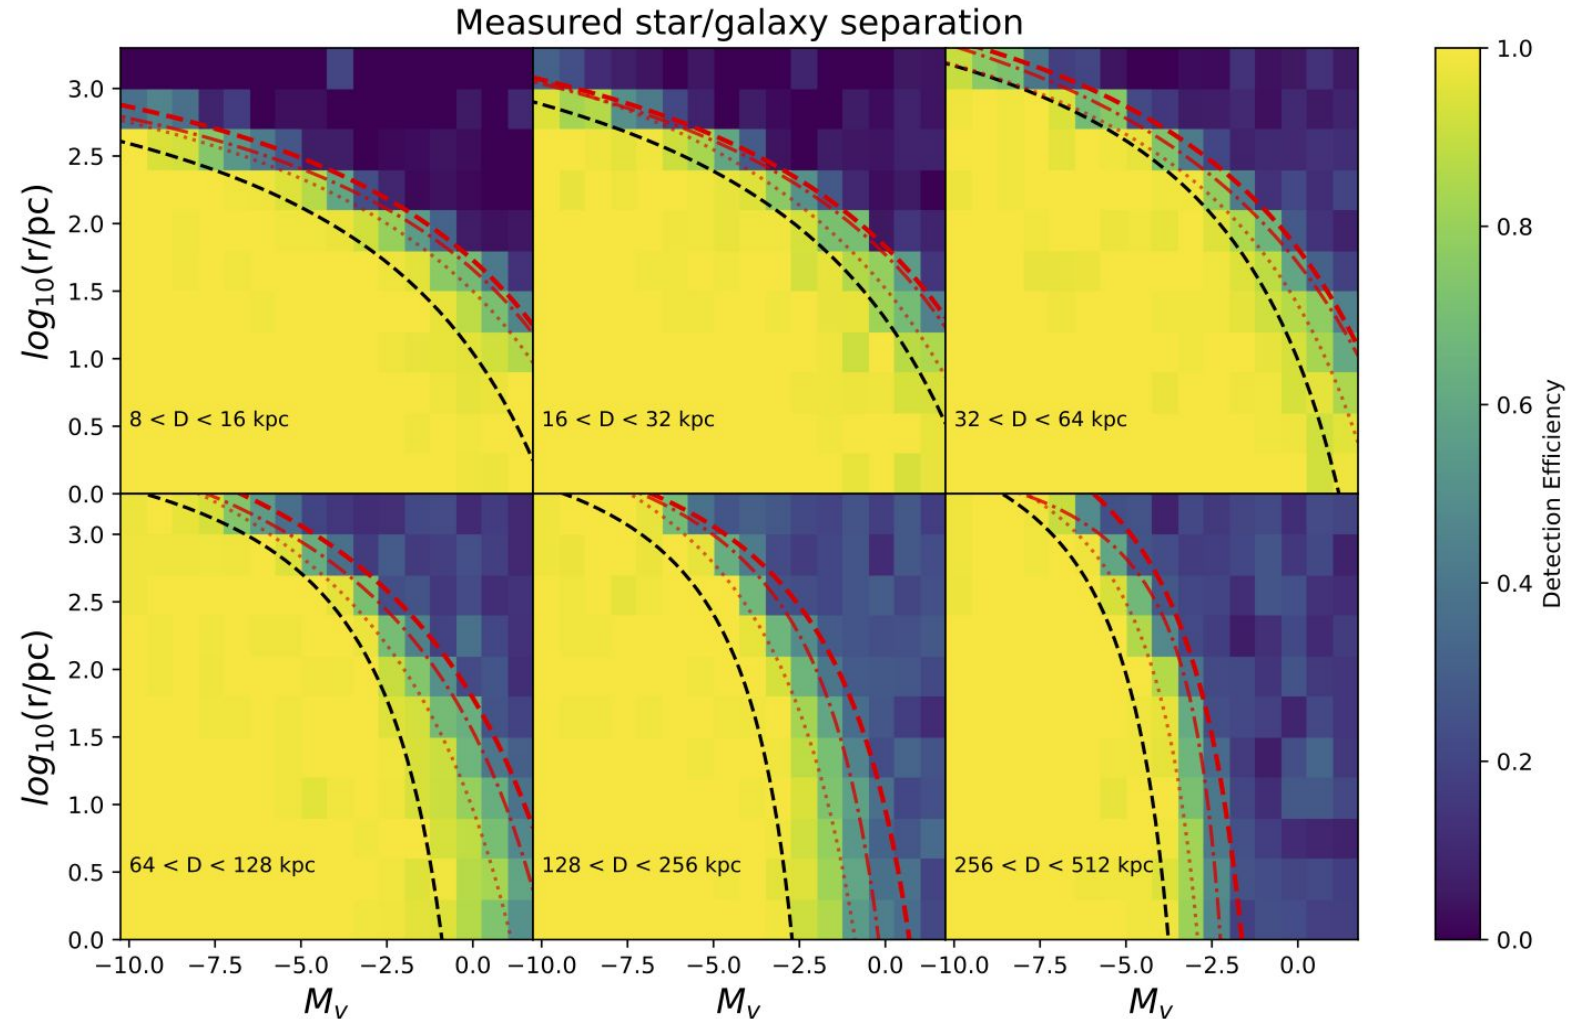

Star/galaxy separation

Bechtol+2023; “Roman Core Community Surveys White Paper: Coordinating Roman and Rubin for Cosmic Probes of Dark Matter with Resolved Stellar Populations”
https://asd.gsfc.nasa.gov/roman/wps_2023/files/016_Bechtoll_HLWAS.pdf

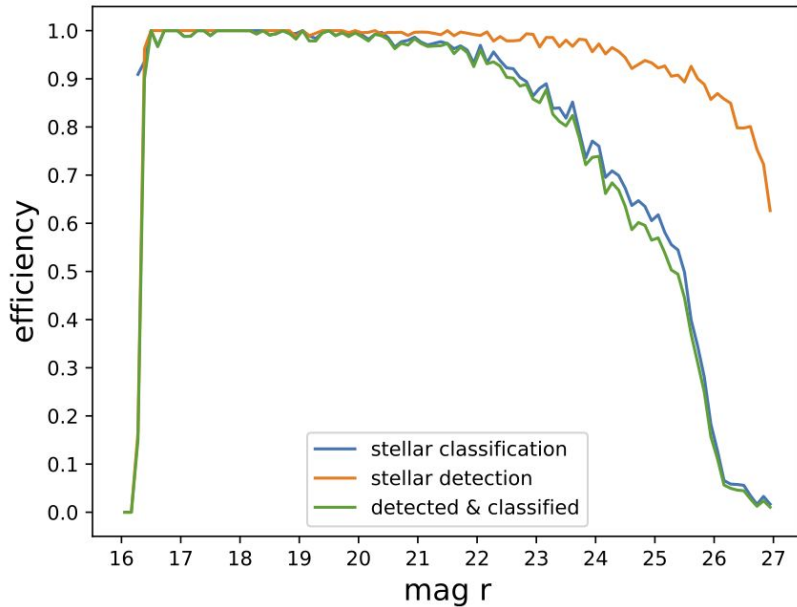

Injected 10^5 artificial dwarfs
into Rubin Data Preview 0
(simulated) dataset

Run dwarf galaxy detection
algorithm, measure
efficiency vs. distance,
luminosity, half-light radius

Star/galaxy separation

Tsiane, Drlica-Wagner+ in prep

Detecting dwarfs, star clusters, and streams

Matched filter searches miss objects with a lot of unresolved emission

Many studies rely on visual inspection to find dwarfs and streams

Confirmation often requires space-based (HST, JWST) follow-up

Dwarf galaxy near NGC 2403

($D \sim 3.2$ Mpc, $M_* \sim 7 \times 10^9 M_{\text{Sun}}$; $\sim 2.5 M_{*,\text{LMC}}$)

MADCASH

J074238+652501-dw

$M_V \sim -7.8$

$r_{\text{half}} \sim 179$ pc

$R_{\text{proj}} \sim 35$ kpc from NGC 2403

(aka "MADCASH-I")

Carlin+2016, ApJL, 828, 5

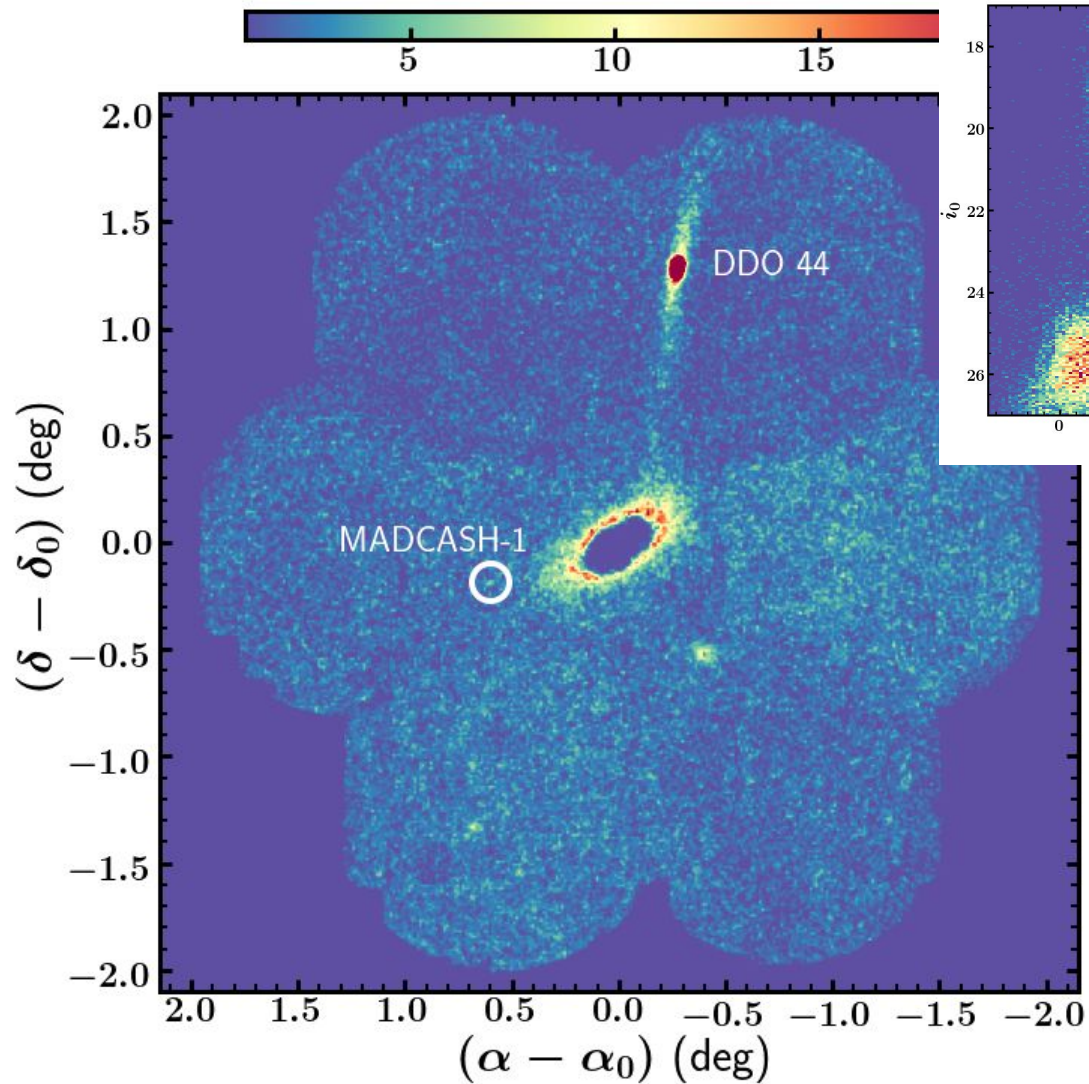

Subaru/HSC

HST/ACS

Carlin+2021, ApJ, 909, 211

NGC 2403 ($M_* \sim 3 M_{*,\text{LMC}}$) dwarf satellites

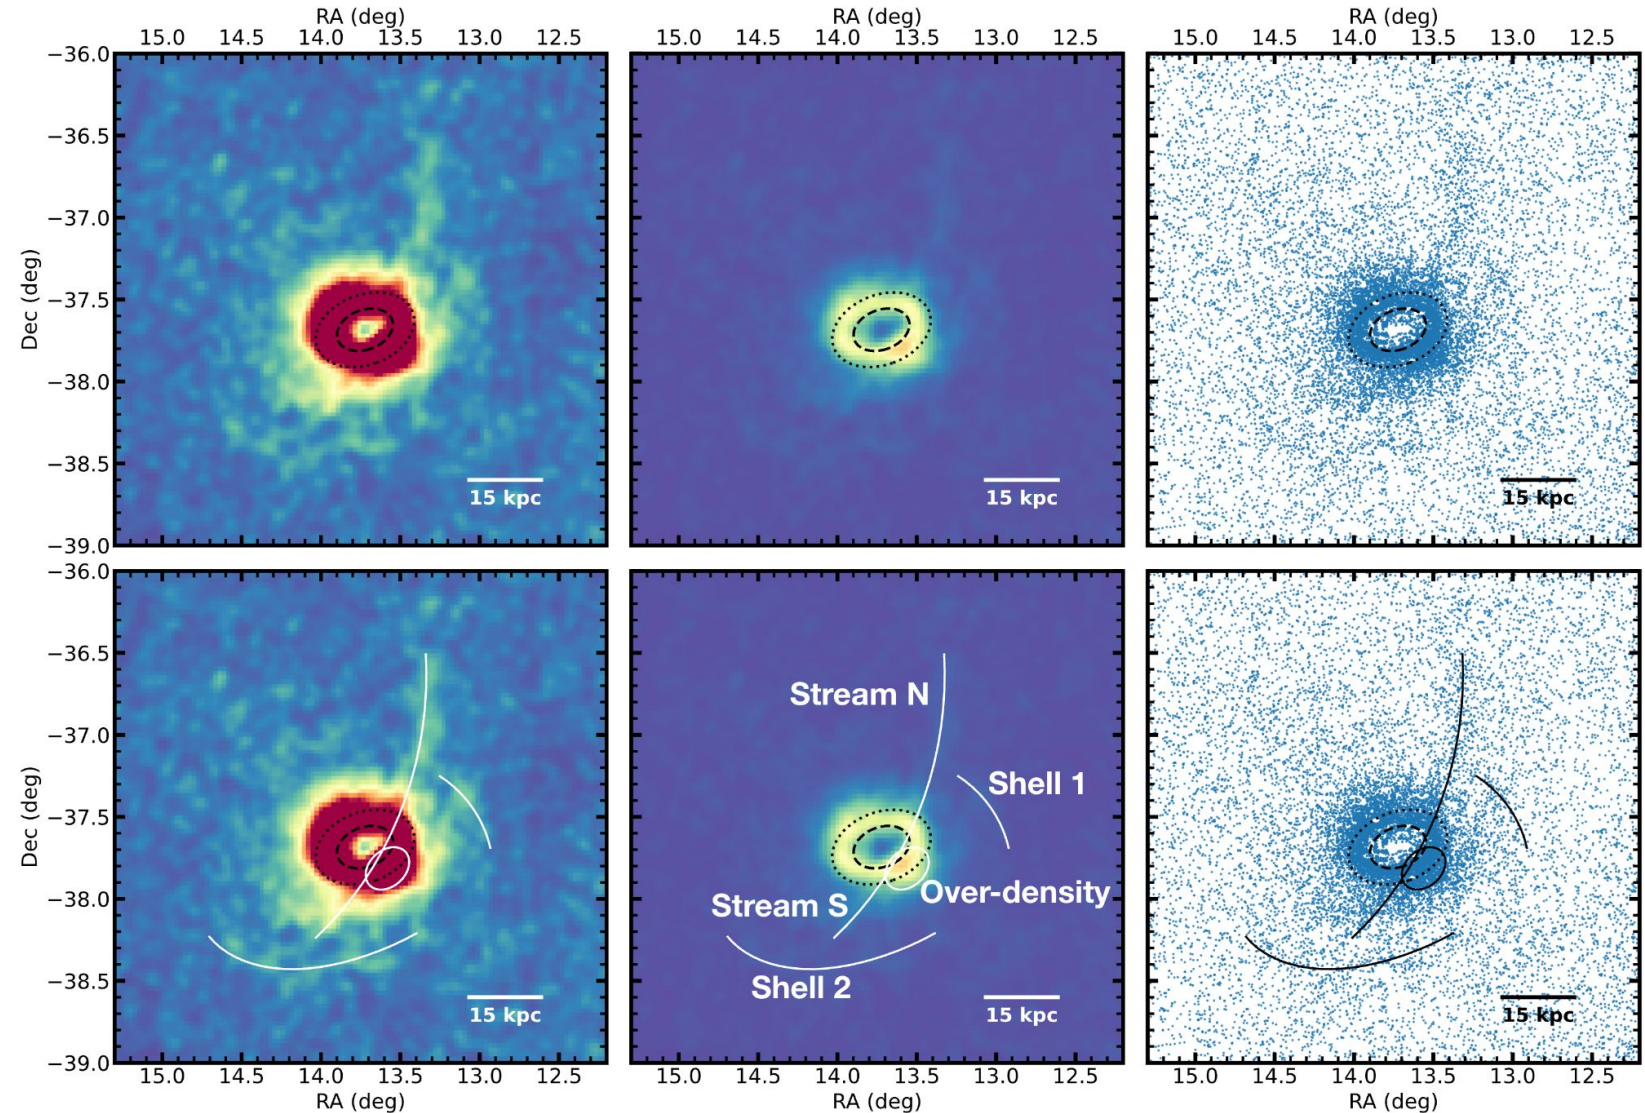

DDO 44 is tidally disrupting! Total luminosity (dwarf+tails)
 $M_V \sim -12.9$. Such pairings (NGC2403+DDO44) are
 extremely rare in Illustris models.

Carlin+2019 (ApJ, 886, 109)

NGC 300 (~LMC mass) – tidal stream/debris found in DELVE-DEEP data

See Cat Fielder's
poster for details!

(and Fielder+2024,
in prep)

Dwarf galaxy near NGC 4214

($D \sim 2.9$ Mpc, $M_* \sim 1 \times 10^9 M_{\text{Sun}}$; $\sim 0.4 M_{*,\text{LMC}}$)

← NGC 4214

MADCASH J121007+352635-dw

$M_V \sim -9.2$

$r_{\text{half}} \sim 131$ pc

$R_{\text{proj}} \sim 70$ kpc from NGC 4214

(aka "MADCASH-2")

10 arcsec

Subaru/HSC

HST/ACS

Carlin+2021, ApJ, 909, 211

Surprising results among satellites of nearby ~LMC hosts: young stellar populations in MADCASH-2

- ~10% of its stellar mass formed in the past ~1.5 Gyr
- No neutral hydrogen detected ($M_{\text{HI}} < 4.8 \times 10^4 M_{\text{sun}}$)

observed

ancient + 10%
intermediate +
1% young

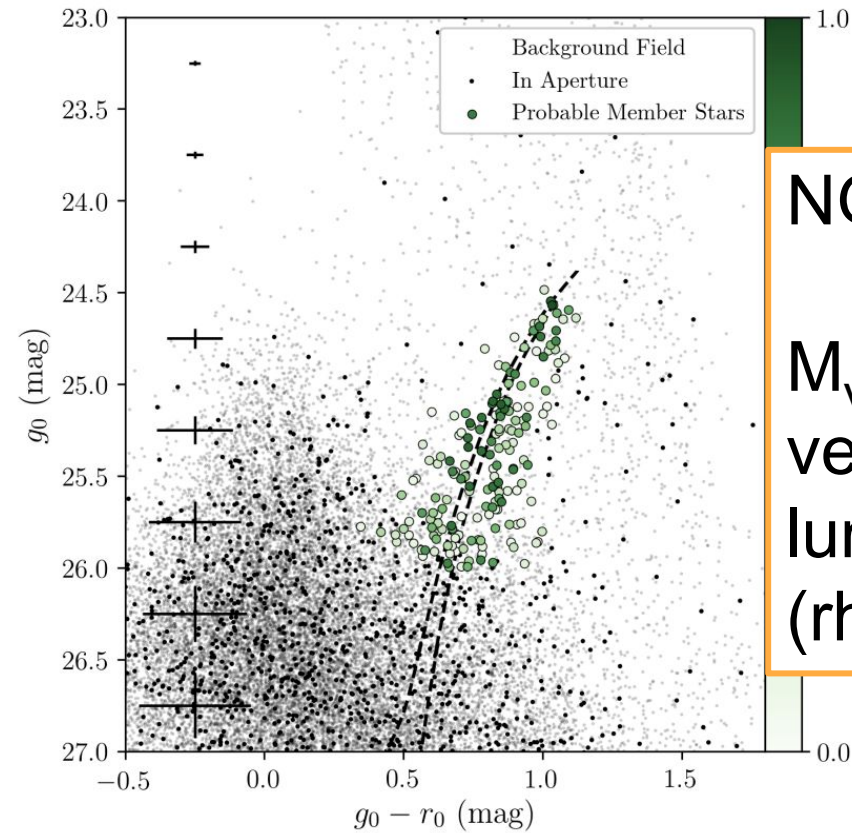

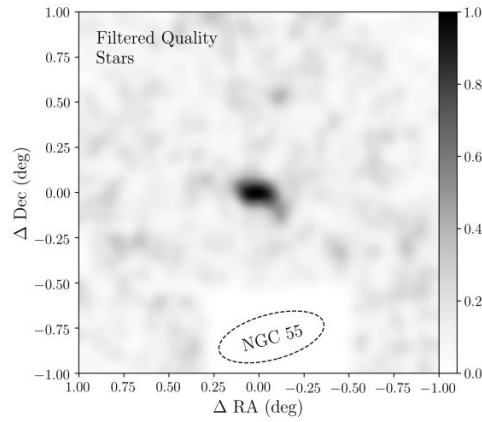

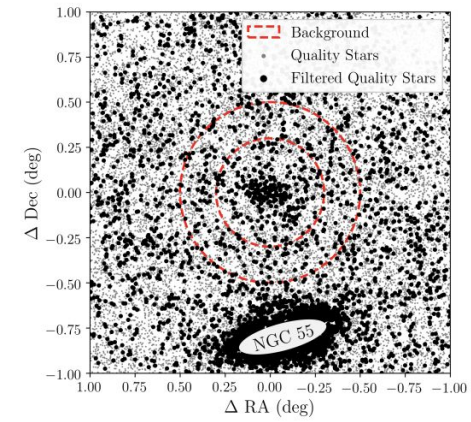

model with
only ancient
populations

See Carlin+2021,
ApJ, 909, 211

Properties measured from HST data:
 $M_V \sim -9.2$
 $r_{\text{half}} \sim 131 \text{ pc}$
 $R_{\text{proj}} \sim 70 \text{ kpc from NGC 4214}$

NGC 55 ($M_* \sim M_{*,\text{LMC}}$) dwarf satellite

NGC 55-dw1:
 $M_V = -8.0$,
very large for its
luminosity
($r_{\text{half}} \sim 2.2$ kpc)

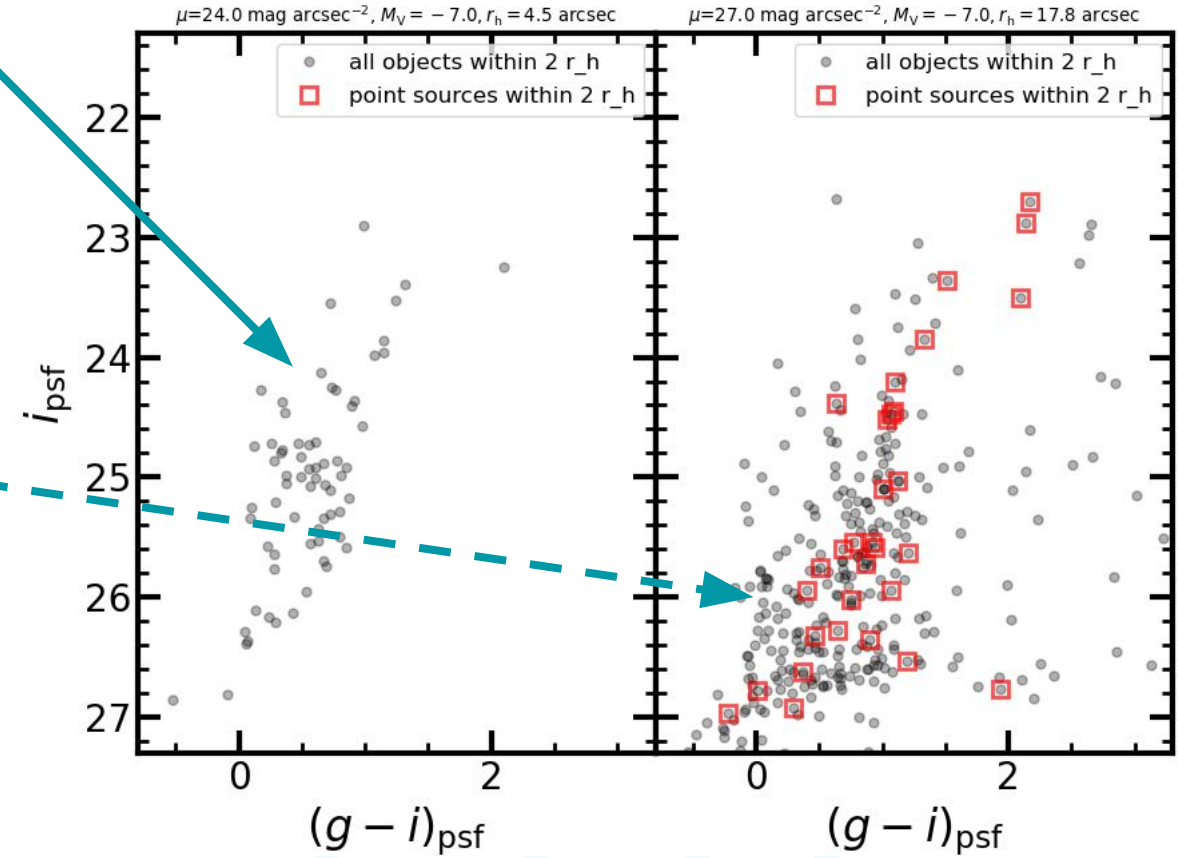

McNanna+2024 (ApJ 961, 126)

Most of these Local Volume dwarfs are discovered from the ground, but require space-based follow-up to confirm+characterize. How do we deal with this in the LSST era?

Detecting “partially resolved” dwarfs

ongoing work (with Peter Ferguson – see his poster!):

1. inject dwarfs into Subaru+HSC images
2. train an RCNN to identify them
3. (search for dwarfs over the full LSST footprint)

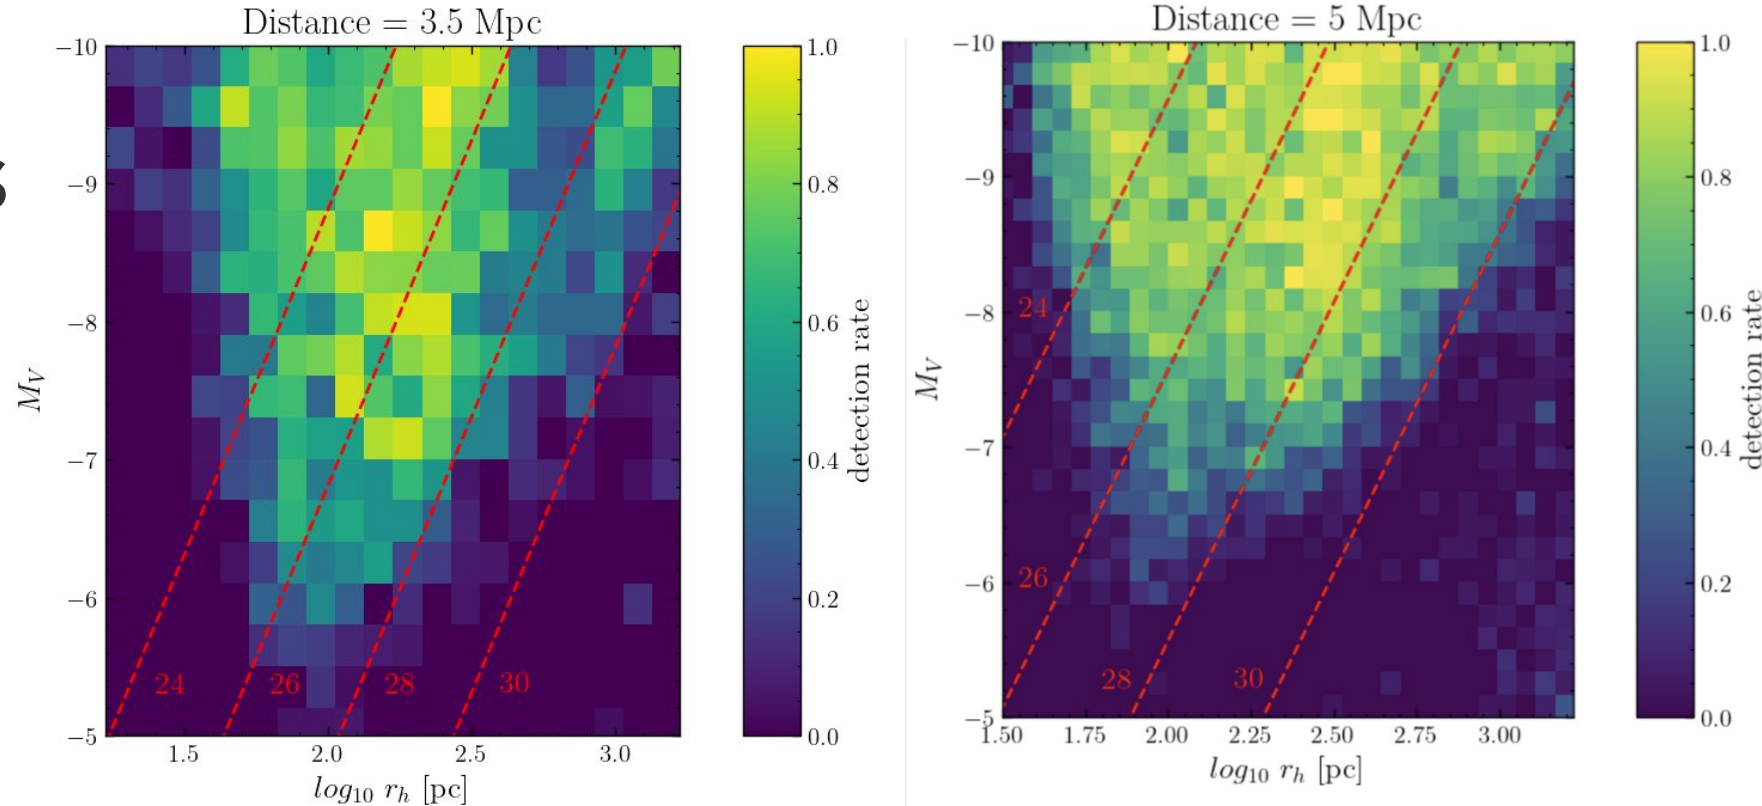

Detecting “partially resolved” dwarfs

ongoing work (with Peter Ferguson – see his poster!):

1. inject dwarfs into Subaru+HSC images
2. train an RCNN to identify them
3. (search for dwarfs over the full LSST footprint)

recovery rate at two distances:

Recovering fainter, and more compact, dwarfs than matched-filter detection!

LSST proper motions

Expected proper motion precision:

Proposal: improve LSST proper motions by using DECam data as baseline (A. Drlica-Wagner, G. Bernstein, et al.)

- Provides high-precision proper motions early in the survey (possibly DR1 or DR2)
- Longer baseline significantly increases the precision

Optimizing background subtraction for LSB science

Aihara+2019, PASJ, 71, 114

Watkins+2024,
MNRAS, 528, 4289

Kelvin+2023,
MNRAS, 520, 2484

RR Lyrae as satellite beacons

Most MW dwarfs have RR Lyrae (e.g.,
Martinez-Vazquez+2019, MNRAS, 490, 2183):

LSST will identify RR Lyrae beyond the MW
virial radius, over $\sim 20000 \text{ deg}^2$ of sky

RR Lyrae as satellite beacons

MW dwarfs at $D > 100$ kpc can be reliably identified as groupings of 2-3 RR Lyrae (within some “linking length” of, e.g., 500 pc; Baker+Willman 2015, AJ, 150, 160). (See also Sanderson+2017, MNRAS, 470, 5014.)

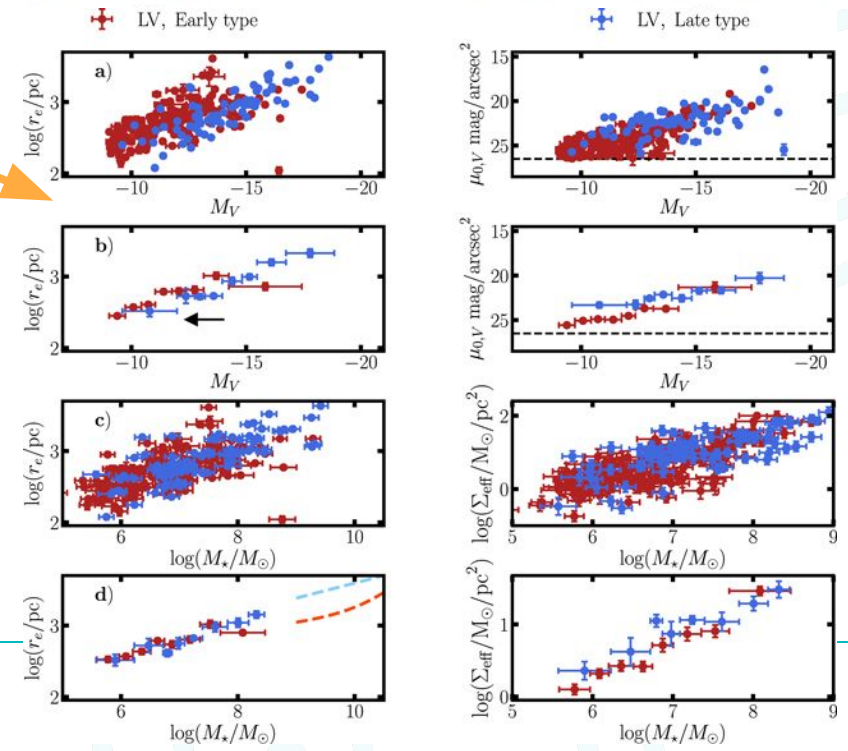

For an example of a dwarf (Leo V; $d \sim 170$ kpc) identified via RR Lyrae, see Medina+2017, ApJL, 845, 10.

Unresolved or partially resolved LSB galaxies

- LSB galaxies in DES – [Tanoglidis+2021 \(ApJS, 252, 18\)](#)
- Local Volume dwarf ($M_V < -9$) satellites using data from DECam, CFHT/Megacam, Subaru/HSC --
[Greco+2018 \(ApJ, 857, 104\)](#); [Carlsten+2021 \(ApJ, 922, 267\)](#); [Carlsten+2020 \(ApJ, 891, 144\)](#); [Carlsten+2020 \(ApJ, 902, 124\)](#); [Carlsten+2021 \(ApJ, 908, 109\)](#); [Carlsten+2022 \(ApJ, 933, 47; ELVES\)](#)
- SAGA – spectroscopically confirmed dwarf ($M_V < -12.3$) satellites of 100 MW analogs – [Mao+2021 \(ApJ, 907, 85\)](#); [Geha+2017, \(ApJ, 847, 4\)](#)

Pavo: a blue, star-forming, gas-rich, isolated dwarf at $D \sim 2$ Mpc

Jones+2023 (ApJL, 957, 5)

Found using ML
classification
