**Late-time large-scale structure, Hubble rate**

# Observational Probes

**Huge fraction of the universe left to explore!**

## The high-redshift, large-volume universe is the key to answering foundational questions in cosmology:

- How did the universe transition from neutral to ionized?
- How did galaxies build up stars and evolve to their current state?
- Did the universe begin with inflation?
- What is the nature of dark energy and dark matter?

KICP is playing a major role in developing the technology (on-chip superconducting millimeter-wave spectrometers)

and the observational technique of **line intensity mapping** with a series of experiments (SuperSpec, SPT-SLIM, SPT-3G+, ...)

to efficiently detect the *complete population* of faint, high-redshift galaxies over the full sky.

# The Epoch of Reionization

What did the first galaxies look like? How did they change during the first billion years?

When and how did they drive the phase change? What was the morphology of their interaction with the intergalactic medium?

# The Epoch of Reionization

Neutral hydrogen + a tracer of early galaxies gives the “ultimate” view of reionization dynamics

# Large-Scale Structure Constrains Our Cosmological Model

## Primordial non-Gaussianity

Did inflation involve multiple fields?

## Expansion History

Is the dark energy equation of state ( $w=-1$ ) constant?

## Growth of Structure

Does the neutrino have a normal or inverted hierarchy?

# Why High Redshift?

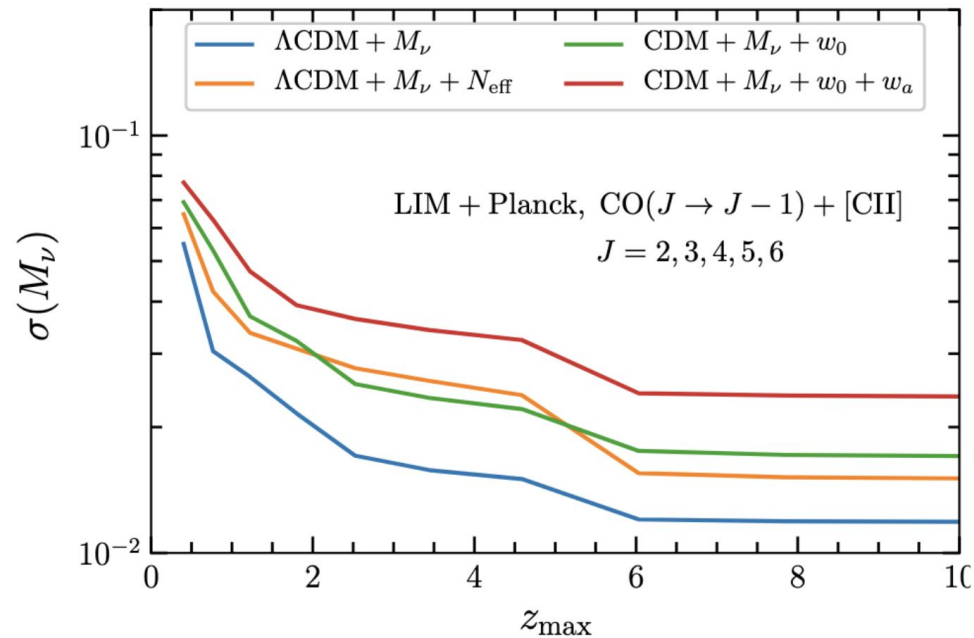

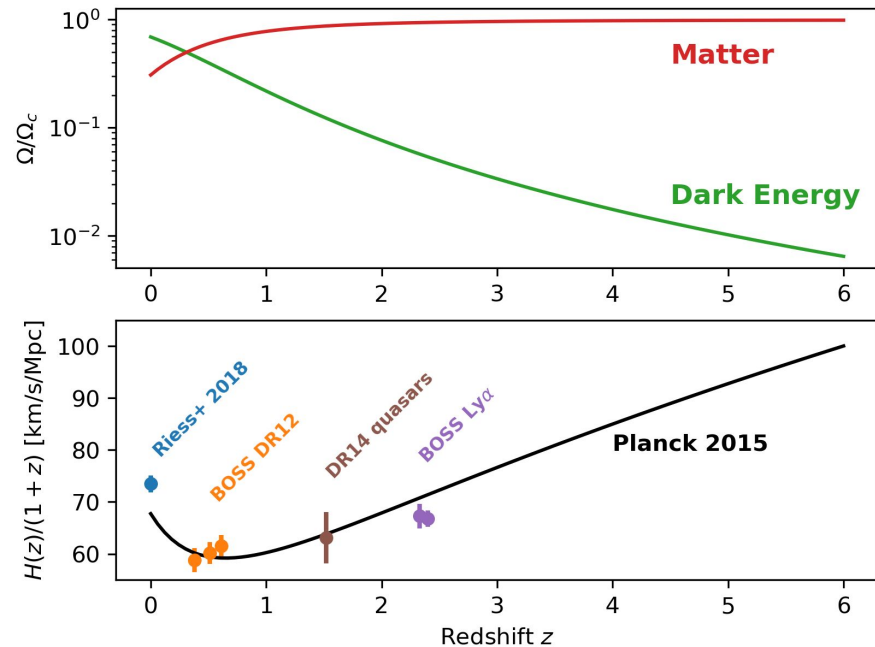

More volume, better statistics.

“Primordial Figure of Merit” scales with precision on inflationary physics

# Why High Redshift?

Wide redshift coverage probes different epochs and alleviates parameter degeneracies.

Moradinezhad Dizgah, Keating, Karkare et al.  
ApJ 2110.000140

# Getting to High Redshift

Why not just use existing galaxy surveys?

- High-redshift galaxies are dust-attenuated and redshifted out of ground-based optical bands
- Objects get fainter at higher redshift and are harder to detect against a noisy background

# Getting to High Redshift

Why not just use existing galaxy surveys?

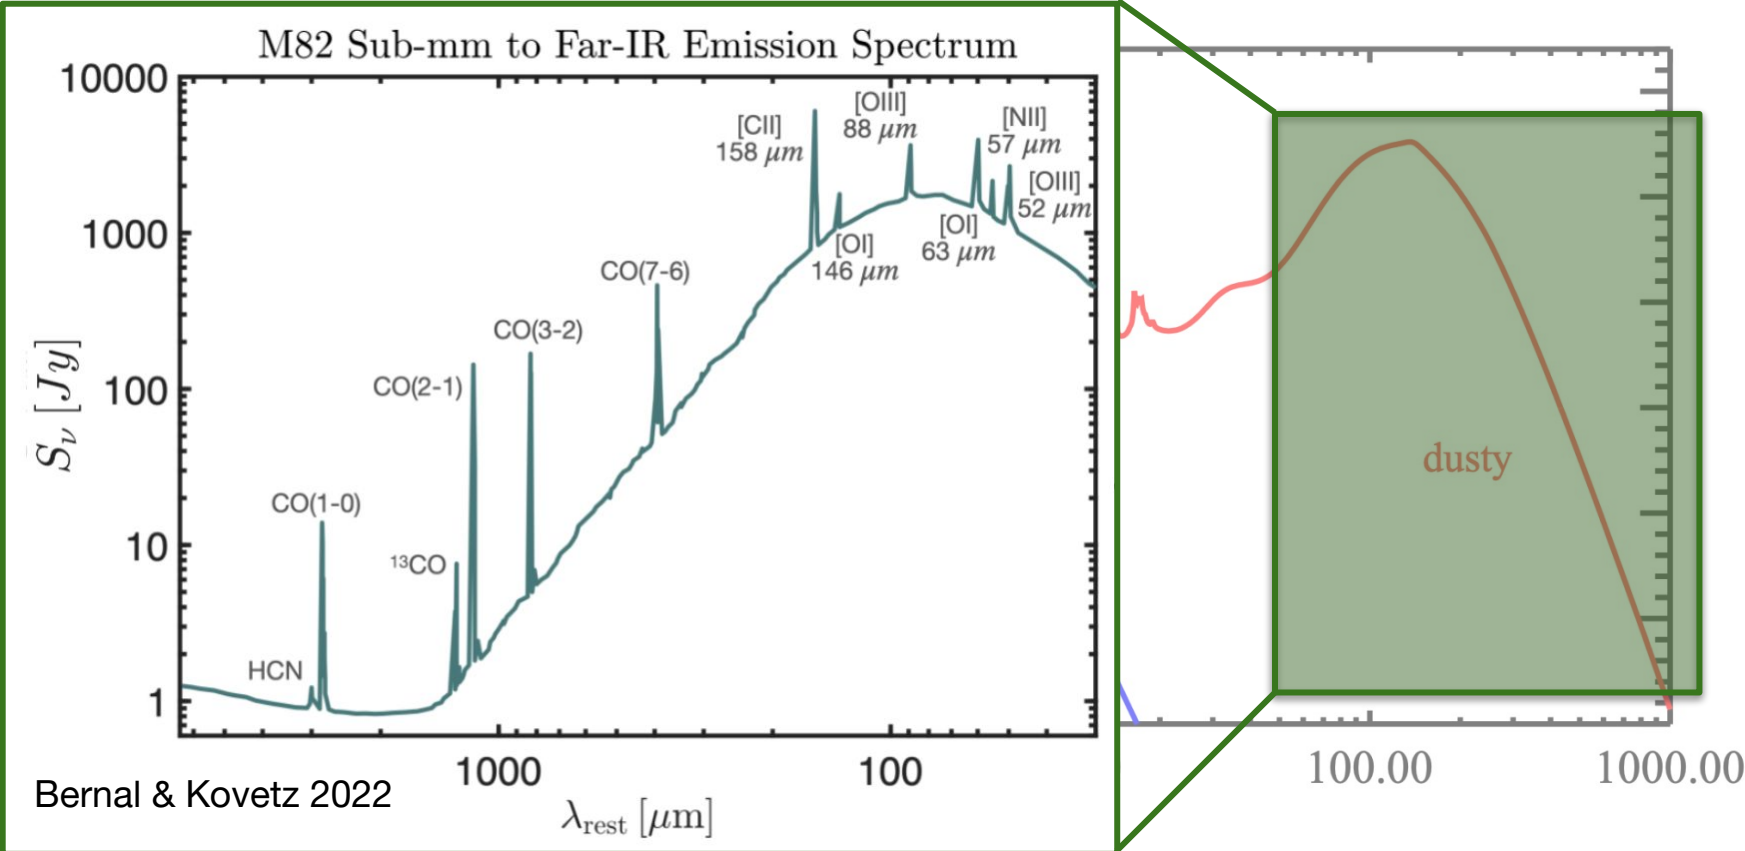

- High-redshift galaxies are dust-attenuated and redshifted out of ground-based optical bands → **millimeter-wave**
- Objects get fainter at higher redshift and are harder to detect against a noisy background → **line intensity mapping**

# SuperSpec (Superconducting Spectrometer)

The image is a screenshot of a news article from the University of Chicago. At the top left is the University of Chicago crest, and at the top center is the text "uchicago news" in a red, serif font. To the right of the text are search and menu icons. The main content area features a large portrait of Erik Shirokoff, a man with short brown hair, wearing a grey suit jacket over a dark shirt, smiling. To the left of the portrait, the text reads: "Erik Shirokoff, astronomer who built instruments to map the universe, 1979-2023". Below this, it says "Remembered as patient and generous teacher and mentor". At the bottom left, a large letter 'A' is followed by the text: "ssoc. Prof. Erik Shirokoff, a University of Chicago astronomer who built instruments to understand the earliest ages of the universe, died Jan. 26. He was 43." At the bottom right, it says "By Louise Lerner Feb 3, 2023".

# Line Intensity Mapping (LIM)

Karkare+ 2203.07258  
mm-wave LIM white paper

Integrate over individual sources while retaining large-scale cosmology.

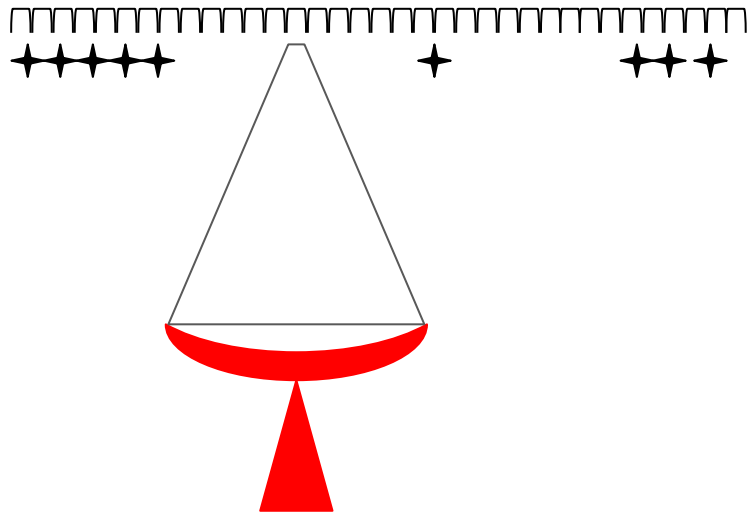

Spectroscopic observations provide redshifts.

Much more efficient than object detection at high redshift (the low-SNR regime).

# Galaxy Detection vs LIM

## Galaxy detection mode:

Use a telescope with high angular resolution (**relatively large dish**) to resolve individual objects.

An object is **detected** when it reaches some threshold (maybe  $5\sigma$ ).

The fundamental data product is a **catalog** of objects.

# Galaxy Detection vs LIM

## Intensity mapping mode:

Use a telescope with lower angular resolution (**small dish**) matched to the scales that you care about.

Every (large) pixel has some noise value.

The fundamental data product is a **map** with error estimates.

# Galaxy Detection vs LIM

Galaxy detection is optimal in the high SNR regime, while intensity mapping is optimal in the low SNR regime (e.g., high redshifts).

Nothing stops us from doing intensity mapping with high-resolution data (just operate on the map before object detection)!

But if we are less interested in small scales, LIM is usually more economical: smaller dish and less observation time needed.

# The South Pole Telescope

Three generations of CMB cameras:  
**SPT-SZ** (2006-2011)  
**SPTpol** (2012-2016)  
**SPT-3G** (2017-)

10m off-axis Gregorian with submillimeter-quality surface accuracy

Optimized for large-scale surveys of faint, diffuse emission (like LIM!)

# Community Support for LIM is Growing

## 4.2.6 – Future Opportunities: Line Intensity Mapping & Gravitational Waves

December 2023: the P5 report endorses LIM as a promising new direction for particle physics!

Line intensity mapping (LIM) techniques are potentially a valuable future method to address key particle physics science cases during the next twenty years by probing the expansion history and the growth of structure deep in the matter-dominated era when the first galaxies were forming. LIM observations of this era could enable tests of the theory of inflation by providing a precise map of the primordial hydrogen gas which is theoretically clean for interpretation. This technique has the potential to access an earlier epoch in the universe than Spec-S5. Work to prove the viability of this method (encompassing both analysis and instrumentation) should continue with multi-agency support (Recommendation 4e), including low-cost instrumentation development competed through the DOE R&D program. DOE has already partnered with NASA to construct one pathfinder LIM experiment, LuSEE-Night, and there are exciting opportunities for investment in ground-based activities in the coming decade.

### **Recommendation 4e:**

Conduct R&D efforts to define and enable new projects in the next decade, including detectors for an  $e^+e^-$  Higgs factory and 10 TeV pCM collider, Spec-S5, DUNE FD4, Mu2e-II, Advanced Muon Facility, and **Line Intensity Mapping** (sections 3.1, 3.2, 4.2, 5.1, 5.2, and 6.3).

# Summary

LIM at mm wavelengths can probe cosmic structure over an extremely wide redshift range from the ground.

We are developing on-chip mm-wave spectrometers to make this measurement:  
**stay tuned for updates from SuperSpec and SPT-SLIM!**

Next-generation LIM experiments will have the sensitivity answer the fundamental mysteries of our cosmological model beyond the reach of CMB and galaxy surveys.

KICP was the perfect place to start a new project and is playing a major role in developing this field!
