

# On Detecting HI in Emission at $z \sim 1$

Nishikanta Khandai

Great Lakes Cosmology Workshop, KICP, Chicago June 16, 2010

Collaborators: Shiv K. Sethi, Tiziana DiMatteo, Rupert Croft

McWilliams Center for Cosmology, Carnegie Mellon University

# Outline

- ▶ Motivation
- ▶ Modeling the HI distribution
- ▶ Prospects for Detection: Statistical and Direct
- ▶ Detecting by Stacking the Spectra
- ▶ Conclusions and Future Prospects

# Motivation

## Evolution of Neutral Hydrogen (HI)

Ali & Bharadwaj 2005

# Motivation

## Evolution of Neutral Hydrogen (HI)

Ali & Bharadwaj 2005

Noterdaeme et al. 2009

- ▶ Post-reionisation, a tiny fraction of neutral hydrogen (HI) survives ionization and is locked in dense clumps through self-shielding : DLAs.
- ▶ The neutral fraction has remained consistent with a constant value of  $\Omega_{HI} \sim \mathcal{O}(10^{-3})$   $z > 1$  with large errors.
- ▶ A census of cold gas is crucial for galaxy formation models at moderate redshifts.
- ▶ Clustering properties of HI selected galaxies (HI bias, mass function), will give key insights into the clustering of their host halos.
- ▶ 21-cm cosmology (Ue-Li Pen's talk), will also put independent constraints on cosmological parameters.

- ▶ We focus in the post-reionization era and make predictions for the distribution of HI in this regime, using the 21cm hyperfine transition of HI as a probe.
- ▶  $T_s \gg T_{CMB}$  at these redshifts hence the signal will be seen in emission.
- ▶ We will see that a direct detection for HI in emission with an existing radio interferometer (GMRT) is not feasible.
- ▶ Noise is too large, flux is diluted at higher redshift.
- ▶ A statistical detection would be possible: low- $\sigma$  detection at  $z = 1.33$ .
- ▶ Strategy for direct detection: Stack the signal with known estimates galaxy redshift from another survey: DEEP2.
- ▶ Independent constraint on  $\Omega_{HI}$

# Modeling the HI Distribution

## Simulation of DLAs at $z=3$

- ▶ Bimodality at  $M \sim 10^{10.5}$
- ▶ Suppression in HI at  $M > 10^{11} M_{\odot}$
- ▶  $10^{13} M_{\odot}$  halo also host the most significant HI.

$$M_{\text{vir}} \simeq 10^{10} M_{\odot} \left( \frac{v_{\text{circ}}}{60 \text{ km/s}} \right)^3 \left( \frac{1+z_c}{4} \right)^{-3/2}$$
$$V_{\text{circ}}^{\text{min}} \sim 30 \text{ km/s} \quad V_{\text{circ}}^{\text{max}} \sim 200 \text{ km/s}$$

Pontzen et al 2008

Power et al 2010

- ▶ Observations: HIPASS galaxies at  $z = 0$  (Zwaan et al. 2005)

$$\frac{dn}{d\ln M} = 0.006 \left( \frac{M_{HI}}{M_{HI}^*} \right)^{-0.37} \exp\left(-\frac{M_{HI}}{M_{HI}^*}\right)$$

$$M_{HI}^* = 10^{9.8} M_{\odot}$$

- ▶ Shift due to larger  $\Omega_{HI}(z = 1)$
- ▶ Finite resolution: Mismatch at low masses

# Simulation Details

- ▶ Gadget3: Dark Matter Simulation
- ▶  $N_{part} = 2448^3$ ,  $L_{box} = 400h^{-1} Mpc$ ,  
1.5 larger than Millenium.
- ▶ Cosmology:  $\sigma_8 = 0.8$ ,  $n_s = 0.96$ ,  $\Omega_\Lambda = 0.74$ ,  $\Omega_m = 0.26$   
 $P(k) \Rightarrow$  Eisenstein and Hu.
- ▶ Halofinder: SUBFIND with 20 bound particles.
- ▶ Mass resolution:  $M_{DM} = 3 \times 10^8 M_\odot$ ,  
3 times finer than Millenium.
- ▶ Large volume will probe effects of cosmic variance on  $\Omega_{HI}$

$$\triangleright M_{HI} \propto \frac{(M_{halo})^m}{1 + \left(\frac{M_{halo}}{M_{min}}\right)^n + \left(\frac{M_{halo}}{M_{max}}\right)^p}$$

- ▶ Model 1: Fits Zwaan mass function but normalised to  $\Omega_{HI} = 1.2 \times 10^{-3}$
- ▶ **Model 2**: HI suppression in low mass halos.
- ▶ **Model 3**: HI suppression in high mass halos.

Table: Model Parameters

Model	$M_{min}(10^{10} M_{\odot})$	$M_{max}(10^{10} M_{\odot})$	m	n	p
1	12	143	1.8	1.36	1.8
<b>2</b>	12	143	2.0	1.36	2.0
<b>3</b>	5	143	1.6	1.15	1.7

Color code: HI fraction  $f_{HI}$

# Statistical and Direct Detection Estimates

- ▶ Observation time (statistical and direct) too large.
- ▶ Individual detection: no constraints on  $\Omega_{HI}$
- ▶ Signal  $\mathcal{O}(10\mu Jy)$ , Noise  $\mathcal{O}(mJy)$
- ▶ Beat noise by stacking sources, with independant redshift estimate.

# Stacked Spectra

$$S_{\nu} = \frac{3}{4} A_{12} h \nu \frac{M_{HI}}{m_H} \frac{(1+z)}{4\pi D_L(z)^2} \phi(\Delta\nu) \quad (1)$$

$$\Delta\nu = \frac{\Delta v}{c} \nu \quad (2)$$

# Effect of z-errors in DEEP2

Spectral resolution in DEEP2: 68km/s

## DEEP2 (top) and GMRT common field of view

## Summary and Ongoing Efforts

- ▶ We have modelled HI in a Dark Matter Simulation and seen how the signal can be extracted by stacking sources.
- ▶ In a preliminary estimate we find that DEEP2 and GMRT have around 2000 sources in common.
- ▶ Redshift errors might dilute the expected signal.
- ▶ By combining different subsets in the sample we can expect (in principle) to constrain the HI mass function at  $z \sim 1$ .
- ▶ We will also be estimating whether such a strategy can be carried out with photo-z in a survey like LSST (larger sample but larger z-errors).
