Probing the Early Universe with Dark Matter

LSST Dark Matter Workshop KICP, Chicago August 6, 2019

What happened before BBN?

- The (mostly) successful predictions of the primordial abundances of light elements tell us that the Universe was radiation dominated during BBN.
- But we have good reasons to think that the Universe was not radiation dominated before BBN.
- Primordial density fluctuations point to inflation.
- Other scalar fields or massive particles may dominate the Universe after the inflaton decays.
- The string moduli problem: scalars with gravitational couplings come to dominate the Universe before BBN.

The gap: $10^{16} \,\mathrm{GeV} \gtrsim T \gtrsim 0.003 \,\mathrm{GeV}$

Why should the DM community care about this gap?

sets the abundance of dark matter: there are thermal relics with m_{\chi} > 100 TeV!
sets the size and abundance of the smallest dark matter halos
changes dark matter annihilation morphology, mimicking decaying dark matter
dark matter is the best probe we have of the later stages of inflation and the gap

Part I Probing Inflation with Minihalos

UCMH Formation

If a region has an initial density $\rho > 1.001\bar{\rho}$, then all the dark matter in that region collapses at early times ($z \gtrsim 1000$) and forms an Ultra-Compact Minihalo. Ricotti & Gould 2009

UCMH Formation

Astrometric Microlensing by UCMHs

Probing the Primordial Perturbations

An upper bound on the UCMH number density leads to an upper bound on the primordial power spectrum.

If Gaia doesn't detect microlensing by UCMHs,

Most conservative case: Fermi gives a stronger bound if DM self-annihilation diminishes lensing signal.

Li, ALE, Law 2012

UCMHs Probe Power Spectrum

If dark matter is a thermal relic, the fact that Fermi-LAT has not found any UCMHs gives a powerful bound on P(k).

Josan & Green 2010; Bringmann, Scott, Akrami 2012

UCMHs Probe Power Spectrum

If dark matter is a thermal relic, the fact that Fermi-LAT has not found any UCMHs gives a powerful bound on P(k).

Josan & Green 2010; Bringmann, Scott, Akrami 2012

These bounds (and our Gaia projections) assume that UCMHs have a radial-infall density profile.

UCMH Density Profiles: Spike

Nine simulated UCMHs
 All have similar density profiles:
 $\rho = \frac{\rho_s}{(r/r_s)^{1.5}(1+r/r_s)^{1.5}}$ Stable with redshift, unless there's a merger....
 Adrienne Erickcek

Implications for P(k) bounds

- UCMHs that form from spikes in the primordial power spectrum have Moore profiles ($\rho \propto r^{-1.5}$), while plateaus in the primordial power spectrum generate UCMHs with NFW profiles ($\rho \propto r^{-1}$).
- The dark matter annihilation rate within the UCMHs is reduced by a factor of 200, which reduces upper bound on UCMH abundance by a factor of 3000.
- But we have so many more halos to consider...

Implications for P(k) bounds

Implications for P(k) bounds

• UCMHs that form from spikes in the primordial power spectrum have Moore profiles ($\rho \propto r^{-1.5}$), while plateaus in the primordial power spectrum generate UCMHs with NFW profiles ($\rho \propto r^{-1}$).

• The dark matter annihilation rate within the UCMHs is reduced by a factor of 200, which reduces upper bound on UCMH abundance by a factor of 3000.

But we have so many more halos to consider...

Adrienne Erickcek

 To use these later-forming halos, we need a model to link halo density to formation time.

 $r_s \propto a_c/k_s \qquad \rho_s \propto \bar{\rho}_0 a_c^{-3}$ See Delos, Bruff, ALE (2019) for improved model. • We then use statistics of peaks to get the number density of halos as a function of formation time.

New Constraints on P(k) Delos, ALE, Bailey, Alvarez PRD (2018) 1806.07389

As a proof of concept, we apply this method to a delta-function spike in the primordial curvature power spectrum:

$$\mathcal{P}_{\zeta}(k) = \mathcal{A}_0 k_s \delta(k - k_s)$$

For comparison, we also use the BSA 2012 UCMH abundance constraints to obtain a bound on this power spectrum.

 Including all minihalos more than compensates for the reduction in minihalo luminosity due to the shallower density profiles.

Generalization to different power spectra is underway.

Nonthermal dark matter

- Dark matter may have been created directly from the decay of the heavier particle that dominated the Universe during the EMDE.
- Without fine-tuning, DM will be relativistic when produced.
- Assume decay into two DM particles; unique distribution function from the timing of decays.

Carisa Miller, ALE coming soon

Probing nonthermal DM production

- We can use probes of small-scale structure to constrain the nonthermal production of dark matter.
- Use CLASS to determine matter power spectrum.
- Free-streaming length predicts suppression scale.
- Bounds from Lyman-Alpha forest. Murgia et al. 2018

DM Annihilation within Microhalos

Dark matter annihilation within early-forming microhalos dominates all other emission, mimicking the signal of decaying dark matter.

- Annihilation rate per DM mass is set by the density within the first halos and is constant in time and space.
- Can translate into an effective decay rate and compare to observational bounds on decaying dark matter (with twice the mass).
- For hidden sector dark matter, the isotropic gamma-ray background provides powerful constraints.

Blanco, Delos, ALE, Hooper 2019

Microhalos within Galaxies

Dwarf spheroidal galaxies also provide constraints (and a potential unique signature). Microhalos within these systems will be stripped by tidal forces and stellar encounters, reducing their J-factor.

Observational Signatures and Constraints

Case study: Draco

Microhalos in the central region are disrupted, reducing the annihilation signature.

Sten Delos, ALE,Tim Linden, coming soon

Observational Signatures and Constraints

Case study: Draco

Microhalos in the central region are disrupted, reducing the annihilation signature.

Fermi-LAT observations of Draco limit this emission profile, leading to constraints on EMDE cosmologies.

Summary: Mind the Gap after Inflation

• There is a gap in the cosmological record between inflation and the onset of Big Bang nucleosynthesis: $10^{16} \text{ GeV} \gtrsim T \gtrsim 0.003 \text{ GeV}$

• Dark matter microhalos offer hope of probing the gap.

- An early matter-dominated era (EMDE) enhances the growth of subhorizon density perturbations, boosting the DM annihilation rate.
- We can use gamma-ray observations, the Ly-A forest, and the smallest observed halos to probe the evolution of the early Universe and the origins of dark matter.
- Nonthermal DM production can be constrained by LSST.

Minihalos also probe inflation, but we need to use the right density profile.

UCMH Density Profiles: Plateau

We also formed UCMHs using a plateau feature

UCMH Density Profiles: Plateau

We also formed UCMHs using a plateau feature

and these UCMHs have NFW proflies!

The Microhalo Abundance

To estimate the abundance of halos, we use the Press-Schechter mass function to calculate the fraction of dark matter contained in halos of mass M.

Beware halo formation during the EMDE; it heats your dark matter!

- For WIMP dark matter thermally produced during an EMDE, microhalos form during matter domination.
- With HS dark matter, we can form halos earlier, during radiation domination! *Blanco*, *Delos*, *ALE*, *Hooper 2019*

Estimating the Boost Factor

- Dark matter annihilation rate: $\Gamma = \frac{\langle \sigma v \rangle}{2m_{\chi}^2} \int \rho^2(r) d^3 r \equiv \frac{\langle \sigma v \rangle}{2m_{\chi}^2} J$ Halo filled with microhalos: $J = NJ_{\rm micro} + 4\pi \int_{0}^{R} (1 - f_0)^2 \rho_{\rm halo}^2(r) dr$ Number of microhalos:
- $N = \int (\text{survival prob.}) \frac{M_{\text{halo}}}{M} \frac{df}{d\ln M} d\ln M$

- Assume microhalo NFW profile with c = 2 at formation redshift. Anderhalden & Diemand 2013
- early forming microhalos: $z_f \gtrsim 50$ Ishiyama 2014
- dense cores: $\bar{\rho}_{\rm micro}(r_s) > 2\bar{\rho}_{\rm halo}(r)$ for $r > 1\,{\rm kpc}$
- assume that microhalo centers survive outside of inner kpc: reduces number of microhalos by 1%.
- assume that microhalos are stripped to $r = r_s$: reduces $J_{\rm micro}$ by <20%

Estimating the Boost Factor
